

A MODERN THEORETICAL APPROACH TO THE R-MATRIX AND THE COMING EDA6 LOS ALAMOS IMPLEMENTATION

Outline

- Overview
 - ▣ History at LANL
 - ▣ Updated analyses
- Modern Green-function R-matrix formalism
 - ▣ Bloch formalism: single-channel; multichannel
 - ▣ Multichannel unitarity
 - ▣ Relativistic parametrization
- EDA6
 - ▣ Code features & desiderata
- Resonance parameters
 - ▣ Brune alternative parametrization
 - ▣ vs. S-/T-matrix poles

An immodest proposal:
Consider the model independent
S-/T-matrix poles for
verification of analyses

Overview of multichannel reaction analysis

- History of **E**nergy **D**ependent **A**nalysis
 - Developers: D. Dodder, K. Witte, G. Hale, A. Sierk, MP
 - originally motivated by hadronic analyses e.g. $\pi N \rightarrow \pi N$
 - Origin of relativistic parametrization
 - EDA5 F77; EDA6 F90/95 (targeted for '17)
- Overview
 - EDA5/6 implement Wigner/Eisenbud/Bloch phenomenological R matrix
 - Handles large number of two-body partitions & channels, including EM
 - Data: elastic, inelastic, reaction; diff'l, integrated, total, polarization
- Existing analyses to date...

EDA Existing Analyses

A	System	Channels	Energy Range (MeV)
2	N-N	p+p; n+p,	0-30
		γ +d	0-40
3	N-d	p+d; n+d	0-4
4	⁴ H	n+t	0-20

Recent updates (listed by target nucleus)

^1H : (n,n), (n, γ) < 200 MeV

^6Li : (n,n), (t,t), (t,n) $E_t < 14$ MeV; (n,n), (n,t), (n,d) $E_n < 4$ MeV

^7Be : elastic, (n, γ), (n,tot), (n, α) < 20 MeV

^9Be : angular distributions

^{10}B : < 5 MeV

^{12}C : elastic, (n,tot), (n,n') < 6.5 MeV

^{13}C : (n,tot), (n, γ) < 20 MeV

^{16}O : elastic, (n, α), (n,tot), (n, γ) < 9 MeV

The canonical EDA “modern” R-matrix slide

\mathcal{I}

INTERIOR (Many-Body) REGION
(Microscopic Calculations)

$$|\psi^+\rangle = (H + \mathcal{L}_B - E)^{-1} \mathcal{L}_B |\psi^+\rangle$$

SURFACE

$$\mathcal{L}_B = \sum_c |c\rangle \left(d \left(\frac{\partial}{\partial r_c} r_c - B_c \right) \right),$$

$$\langle \mathbf{r}_c | c \rangle = \frac{\hbar}{\sqrt{2\mu_c a_c}} \frac{\delta(r_c - a_c)}{r_c} \left[(\phi_{s_1}^{\mu_1} \otimes \phi_{s_2}^{\mu_2})_s^\mu \otimes Y_l^m(\hat{\mathbf{r}}_c) \right]_J^M$$

$$R_{c'c} = \langle c' | (H + \mathcal{L}_B - E)^{-1} | c \rangle = \sum_\lambda \frac{\langle c' | \lambda \rangle \langle \lambda | c \rangle}{E_\lambda - E}$$

\mathcal{E}

ASYMPTOTIC REGION
(S-matrix, phase shifts, etc.)

$$\langle r_{c'} | \psi_c^+ \rangle = -I_{c'}(r_{c'}) \delta_{c'c} + O_{c'}(r_{c'}) S_{c'c}$$

or equivalently,

$$\langle r_{c'} | \psi_c^+ \rangle = F_{c'}(r_{c'}) \delta_{c'c} + O_{c'}(r_{c'}) T_{c'c}$$

Measurements

Toy model example: single channel, s-wave, neut.

First solve a problem with a simple BC:

$$(H - E_\lambda)\psi_\lambda(r) = 0$$

$$\left. \frac{d}{dr} r\psi_\lambda(r) \right|_{r=a} = 0$$

Q: What is the spectrum?

$$\int_0^R r^2 dr [\psi_1^*(H\psi_2) - (H\psi_1)^*\psi_2] = -\frac{\hbar^2}{2M} \left[r\psi_1^* \frac{d(r\psi_2)}{dr} - \frac{d(r\psi_1^*)}{dr} r\psi_2 \right]_R$$

A: The above defines a Sturm-Liouville eigenvalue problem implying E_λ are *discrete* – and so **not a scattering problem**

Two essential points

1. Scattering states in general don't satisfy the BC above
2. This implies that the E_λ are not simply related to resonance E

Toy model example: single channel, s-wave, neut.

Now solve it with a more general BC:

$$(H - E_\lambda)\psi_\lambda(r) = 0$$

$$\left. \frac{d}{dr} r\psi_\lambda(r) \right|_{r=a} = B$$

Caveat Emptor: No longer a S-L problem

$$\int_0^R r^2 dr [\psi_1^*(H\psi_2) - (H\psi_1)^*\psi_2] = -\frac{\hbar^2}{2M} \left[r\psi_1^* \frac{d(r\psi_2)}{dr} - \frac{d(r\psi_1^*)}{dr} r\psi_2 \right]_R$$

The RHS doesn't vanish: eigenfunctions not orthogonal

Bloch “fixed” this issue.

Claude Bloch's 1957 paper modernized R-matrix

UNE FORMULATION UNIFIÉE DE LA THÉORIE DES RÉACTIONS NUCLÉAIRES

CLAUDE BLOCH

Centre d'Études Nucléaires de Saclay, Gif-sur-Yvette (S. & O.)

Reçu le 13 avril 1957

A unified formulation of the theory of nuclear reactions

Claude Bloch¹

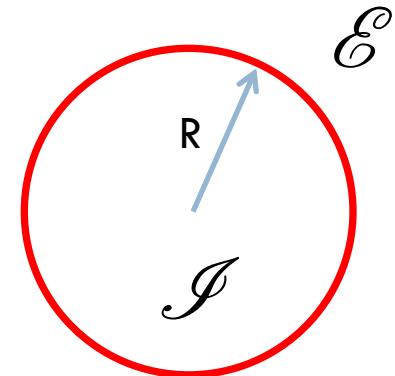

Centre d'Études Nucléaires de Saclay, Gif-sur-Yvette (S. & O.)

$$\int_0^R r^2 dr [\psi_1^* (H \psi_2) - (H \psi_1)^* \psi_2] = -\frac{\hbar^2}{2M} \left[r \psi_1^* \frac{d(r \psi_2)}{dr} - \frac{d(r \psi_1^*)}{dr} r \psi_2 \right]_R$$

NB: The quantity B must be a real constant, indep. of energy in order to obtain an orthonormal basis

$$\mathcal{H} = H + \frac{\hbar^2}{2MR} \delta(r - R) \left[\frac{d}{dr} r - \frac{B}{r} \right]$$

$$\int_0^R r^2 dr [\psi_1^* (\mathcal{H} \psi_2) - (\mathcal{H} \psi_1)^* \psi_2] = 0.$$

Bloch method “builds-in” the finite radius BC

Standard method: solve diff. eqn. in the presence of a BC

$$\begin{aligned} [\mathcal{H} - E] \psi(r) &= f(r), & r < R \\ \frac{\hbar^2}{2MR} \left[\frac{d}{dr} (r\psi(r)) \right]_R &= A, & r = R \end{aligned}$$

Equivalent to:

$$\begin{aligned} [\mathcal{H} - E] \psi(r) &= F(r), & F(r) &= f(r) + A\delta(r - R) \\ \mathcal{H} &= H + \mathcal{L}_0, & \mathcal{L}_0 &= \frac{\hbar^2}{2M} \frac{\delta(r - R)}{R} \frac{d}{dr} r \end{aligned}$$

Representation independence of Bloch operator

- The singular Dirac delta function is only present in the position representation ('R' is the channel radius)

$$\mathcal{L}_B = \frac{\hbar^2}{2M} \frac{\delta(r - R)}{R} \left(\frac{d}{dr} r - B \right)$$

- Equivalent to

$$\hat{\mathcal{L}}_B = \frac{iR^2}{2M} |R\rangle\langle R| \left(\hat{p}_r + iB \right)$$
$$\langle r | \hat{p}_r = \frac{-i}{r} \frac{\partial}{\partial r} r \langle r |$$

- Bloch operator as a projection operator

The scattering matrix

$$R = a$$

- Solve Schrodinger:

$$0 = [H - E] |\Psi\rangle \quad \hat{\mathcal{L}}_L |\Psi\rangle = [H - E + \hat{\mathcal{L}}_L] |\Psi\rangle$$

$$G_L \hat{\mathcal{L}}_L |\Psi\rangle = |\Psi\rangle$$

$$G_L = [H - E + \hat{\mathcal{L}}_L]^{-1}$$

- Scattering BC (single channel, s-wave, neutral):

$$|\mathcal{O}\rangle = | + k \rangle$$

$$|\mathcal{I}\rangle = | - k \rangle$$

$$\hat{\mathcal{L}}_L | + k \rangle = 0$$

$$\hat{\mathcal{L}}_L | - k \rangle = -\frac{ia^2k}{m} |a\rangle \langle a| - k \rangle$$

$$\langle r | \pm k \rangle = \frac{e^{i(\pm k)r}}{r}$$

- Solve for the scattering matrix

$$G_L \hat{\mathcal{L}}_L |\Psi\rangle = |\Psi\rangle$$

$$-i \frac{a^2k}{m} G_L |a\rangle \langle a| - k \rangle = | - k \rangle - S | + k \rangle$$

$$S = \frac{\langle a| - k \rangle}{\langle a| + k \rangle} \left\{ 1 + i \frac{a^2k}{m} \langle a| G_L |a\rangle \right\}$$

Computing $\langle a|G_L|a\rangle$ in an orthonormal basis

- Solve for Schr. eq. for general BC (“B”) interior to CS

$$(H + \hat{\mathcal{L}}_B)|\lambda\rangle = E_\lambda|\lambda\rangle \quad \hat{\mathcal{L}}_B = \frac{ia^2}{2M}|a\rangle\langle a|(\hat{p}_r + iB)$$

$$B^* = B$$

$$S = \underbrace{\frac{\langle a|-k\rangle}{\langle a|+k\rangle}}_{\text{Hard sphere}} \left\{ 1 + i\frac{a^2k}{m}\langle a|G_L|a\rangle \right\}$$

Hard sphere

Poles, cuts

$$G_L^{-1} = H - E + \hat{\mathcal{L}}_L$$

$$\langle a|G_L^{-1}|a\rangle = \sum_{\lambda'\lambda} \langle a|\lambda'\rangle A_{\lambda'\lambda}^{-1} \langle \lambda|a\rangle \quad A_{\lambda'\lambda}^{-1} \equiv \langle \lambda'|G_L^{-1}|\lambda\rangle$$

$$A_{\lambda'\lambda}^{-1} = \langle \lambda'| \left[(H + \hat{\mathcal{L}}_B - E) + (\hat{\mathcal{L}}_L - \hat{\mathcal{L}}_B) \right] |\lambda\rangle$$

$$= (E_\lambda - E)\langle \lambda'|\lambda\rangle + i\frac{a^2}{2m}\langle \lambda'|a\rangle(iL - iB)\langle a|\lambda\rangle$$

$$= (E_\lambda - E)\delta_{\lambda'\lambda} + \gamma_{\lambda'}(B - L)\gamma_\lambda$$

$$= E_\lambda\delta_{\lambda'\lambda} + \Delta_{\lambda'\lambda} - i\Gamma_{\lambda'\lambda}/2 - E\delta_{\lambda'\lambda}$$

$$L \equiv S + iP$$

$$\gamma_\lambda \equiv \frac{1}{\sqrt{2m}}a\langle \lambda|a\rangle$$

$$\Delta_{\lambda'\lambda} = \gamma_{\lambda'}(B - S)\gamma_\lambda$$

$$\Gamma_{\lambda'\lambda} = \gamma_{\lambda'}(2P)\gamma_\lambda$$

Bloch/GF formalism: multichannel, charged case

- Solve Schrodinger knowing External solution ('a' chan. rad.)

$$[H - E]\Psi = 0, \quad [H - E + \mathcal{L}]\Psi = \mathcal{L}\Psi, \quad \Psi = r^{-1} \left[I - OS \right]_{r \geq a}$$

$$\Psi = G\mathcal{L}\Psi, \quad G = [H - E + \mathcal{L}]^{-1}, \quad \mathcal{L} = a^{-1} \left(\rho \frac{\partial}{\partial \rho} - B \right)$$

$$I - OS = R \left(\rho \frac{\partial}{\partial \rho} - B \right) [I - OS], \quad R \equiv G \Big|_{\mathcal{L}}, \quad \rho \frac{\partial}{\partial \rho} O = LO$$

$$S = O^{-1}I + 2i\rho O^{-1}R_L O^{-1}, \quad R_L = [1 + R(B - L)]^{-1}R, \quad \rho \frac{\partial}{\partial \rho} I = LI - 2i\rho O^{-1}$$

- External Coulomb wave function relations

$$O = I^* = G + iF, \quad 1 = GF' - G'F,$$

$$L = \rho O^{-1} \frac{\partial}{\partial \rho} O \equiv S + iP, \quad S = \rho \frac{GG' + FF'}{G^2 + F^2}, \quad P = \rho \frac{1}{G^2 + F^2}$$

Bloch/GF formalism: multichannel unitarity

$$S = O^{-1}I + 2i\rho O^{-1}R_L O^{-1}$$

$$S^\dagger = OI^{-1} - 2i\rho I^{-1}R_L^\dagger I^{-1}$$

$$(M^\dagger)^{-1} = (M^{-1})^\dagger$$

$$S^\dagger S = 1 + 2i\rho I^{-1}R_L^\dagger \left[(R_L^{-1})^\dagger - R_L^{-1} + 2i\rho I^{-1}O^{-1} \right] R_L O^{-1}$$

$$R_L^{-1} = R^{-1} + B - L$$

$$B = B^* \implies L - L^* = 2i\rho I^{-1}O^{-1} \text{ or } P = \rho \frac{1}{G^2 + F^2}$$

$$R_{c'c} = (c' | [H + \mathcal{L} - E]^{-1} | c) = \sum_{\lambda} \frac{\gamma_{c'\lambda} \gamma_{c\lambda}}{E_{\lambda} - E}$$

- Unitarity requires B real
- Energy independent level E_{λ} and reduced width $\gamma_{c\lambda}$ require B constant
- Unitarity is lost if $B = \mathcal{S}(E)$ with constant E_{λ} , $\gamma_{c\lambda}$

Unitarity constraint on T matrix

$$\left. \begin{aligned} \delta_{fi} &= \sum_n S_{fn}^\dagger S_{ni} \\ S_{fi} &= \delta_{fi} + 2i\rho_f T_{fi} \\ \rho_n &= \delta(H_0 - E_n) \end{aligned} \right\} T_{fi} - T_{fi}^\dagger = 2i \sum_n T_{fn}^\dagger \rho_n T_{ni}$$

NB: **unitarity** implies optical theorem $\sigma_{\text{tot}} = \frac{4\pi}{k} \text{Im } f(0)$; but *not just* the O.T.

■ Implications of **unitarity** constraint on transition matrix

1. Doesn't uniquely determine T_{ij} ; highly restrictive, however
Elastic: $\text{Im } T_{11}^{-1} = -\rho_1$, $E < E_2$ (assuming T & P invariance)
Multichannel: $\text{Im } \mathbf{T}^{-1} = -\rho$

2. Unitarity violating transformations

- cannot scale **any** set: $T_{ij} \rightarrow \alpha_{ij} T_{ij}$ $\alpha_{ij} \in \mathbb{R}$
- cannot rotate **any** set: $T_{ij} \rightarrow e^{i\theta_{ij}} T_{ij}$ $\theta_{ij} \in \mathbb{R}$

★ consequence of linear 'LHS' \propto quadratic 'RHS'

3. Unitary parametrizations of data provide constraints that experiment may violate

★ *normalization*, in particular

$$\text{Observable} \propto \text{KF } |T_{fi}|^2$$

Channel radius as *regulator* of the theory

- Simple example: single channel, s-wave, neutral

$$S = O^{-1}I + 2i\rho O^{-1}R_L O^{-1}, \quad B = 0, \rho = ka$$
$$= e^{-2i\rho} \frac{1 + i\rho R}{1 - i\rho R}$$

$$\frac{\partial S}{\partial a} = 0 \implies 0 = \rho R'(\rho) + R(\rho) - \rho^2 R^2(\rho) - 1$$

$$R(\rho) = \rho^{-1} \tan(\rho + f(k))$$

- $f(k)$ is a familiar function – the phase shift

$$f(k) = \delta(k)$$

Complete transition (T) matrix

□ Wolfenstein formalism

$$\langle O_f \rangle = \frac{1}{\text{Tr}(\rho_f)} \text{Tr}(\rho_f O_f) = \frac{1}{\text{Tr}(\rho_f)} \text{Tr}(M \rho_i M^\dagger O_f),$$

$$\rho = aa^\dagger, \text{ and } a_f = Ma_i.$$

$$\text{Using the expansion } \rho_i = \frac{1}{\text{Tr}(\mathbb{1}_i)} \sum_i \langle O_i \rangle O_i,$$

and defining $\text{Tr}(\rho_f) = \sigma_0(\theta)$ gives finally

$$\sigma_0(\theta) \langle O_f \rangle = \frac{1}{\text{Tr}(\mathbb{1}_i)} \sum_i \langle O_i \rangle \text{Tr}(M O_i M^\dagger O_f), \quad \begin{cases} O_i = O_1 \otimes O_2 \\ O_f = O_3 \otimes O_4 \end{cases}$$

$$M_{fi} = \frac{4\pi}{k_i} \langle \phi_{s'}^{\mu'} | \hat{T} | \phi_s^\mu \rangle = \frac{4\pi}{k_i} \sum_{JM'l} \langle \phi_{s'}^{\mu'} | \mathcal{Y}_{Js'l}^M \rangle T_{s'l',sl}^J \langle \mathcal{Y}_{Jsl}^M | \phi_s^\mu \rangle.$$

Lincoln Wolfenstein
1923-2015

Relativistic forms of EDA

$$R = \sum_{\lambda} \frac{\gamma_{\lambda} \gamma_{\lambda}^T}{E_{\lambda}(s) - E(s)},$$

$$s = (p_1 + p_2)^2 = (p_3 + p_4)^2 = (\mathcal{E}_{\text{rel}} + M)^2.$$

Forms for $E_{(\lambda)}(s)$:

a) $\sqrt{s} - M = \mathcal{E}_{\text{rel}}$

b) $\frac{s - M^2}{2M} = \left(1 + \frac{\mathcal{E}_{\text{rel}}}{2M}\right) \mathcal{E}_{\text{rel}}$

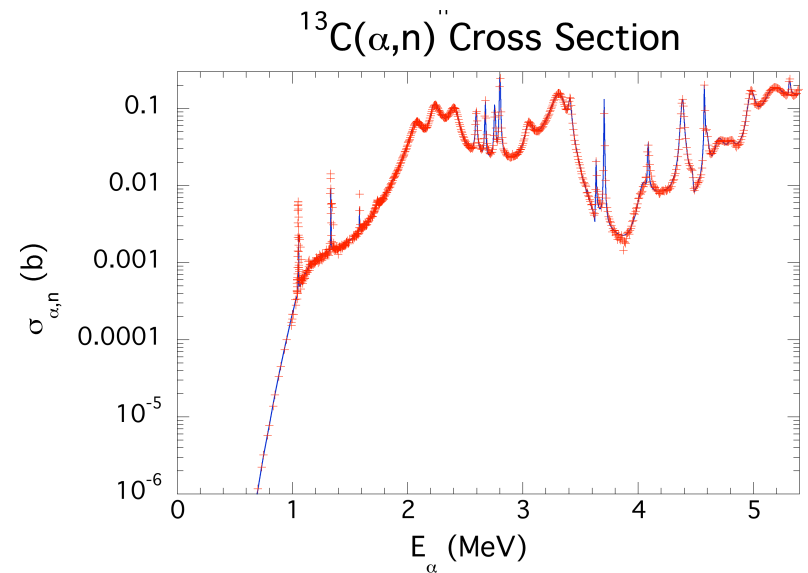

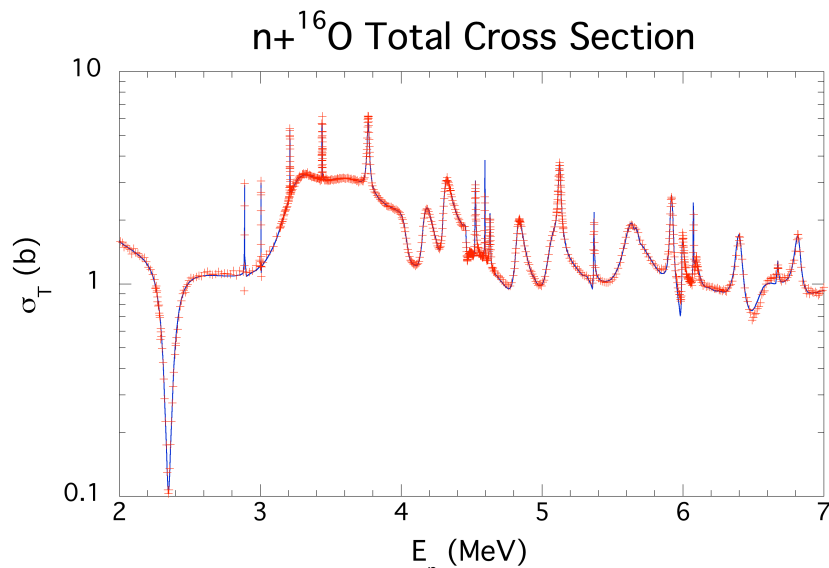

c) $\frac{(s - M^2)(s - \Delta^2)}{8s\mu}$ (Layson)

d) \mathcal{E}_{nr} (norel=1)

$$\left\{ \begin{array}{l} M = m_1 + m_2 \\ \Delta = m_1 - m_2 \\ \mu = \frac{m_1 m_2}{m_1 + m_2} \end{array} \right.$$

Relativistic form: not a luxury

Here is an example from the ^{17}O system: There is a narrow $3/2^+$ resonance at $E_n = 3.0071$ MeV having a c.m. width of 0.33 keV. Relativistically, this resonance would show up at a laboratory α -energy of $E_\alpha = 0.802717$ MeV. Non-relativistically, it would be at 0.803041 MeV. So, the difference is 0.324 keV, or 0.248 keV in the c.m., which is a significant fraction of the width of this resonance.

EM Transitions and Photon Channels

Assume that in the one-photon sector of Fock space, a “wave function” is associated with the vector potential

$$\mathbf{A}_{\mathbf{k}}(\mathbf{r}) = \sqrt{\frac{2}{\pi\hbar c}} \sum_{jm} i^j \left[\alpha_{jm}^{(e)} \mathbf{A}_{jm}^{(e)}(\mathbf{r}) + \alpha_{jm}^{(m)} \mathbf{A}_{jm}^{(m)}(\mathbf{r}) \right],$$

$$\mathbf{A}_{jm}^{(e)}(\mathbf{r}) = \frac{1}{r} \left[u_{ee}^j(\rho) \mathbf{Y}_{jm}^{(e)}(\hat{\mathbf{r}}) + u_{0e}^j(\rho) \mathbf{Y}_{jm}^{(0)}(\hat{\mathbf{r}}) \right], \text{ parity} = (-1)^j,$$

$$\mathbf{A}_{jm}^{(m)}(\mathbf{r}) = \frac{1}{r} u_{mm}^j(\rho) \mathbf{Y}_{jm}^{(m)}(\hat{\mathbf{r}}), \text{ parity} = (-1)^{j+1}.$$

The physical radial functions have the asymptotic forms

$$u_{ii}^j(\rho) = F_j^{(i)} + O_j^{(i)} t_{ii}^j \quad (i = e, m),$$

$$\text{with } O_j^{(m)} = h_j^+(\rho), \quad O_j^{(e)} = -\partial_\rho h_j^+(\rho), \quad \text{and } F_j^{(i)} = \text{Im } O_j^{(i)}.$$

In the usual approach, $O_j^{(e)} = O_j^{(m)} = h_j^+(\rho)$.

Scheme and Properties of the EDA Code

Energy Dependent Analysis Code

- Accommodates general (spins, masses, charges) two-body channels
- Uses relativistic kinematics and R-matrix formulation
- Calculates general scattering observables for $2 \rightarrow 2$ processes
- Has rather general data-handling capabilities (but not as general as, e.g., SAMMY)
- Uses modified variable-metric algorithm that gives parameter covariances at a solution

Uncertainties from Chi-Squared Minimization

$$\chi_{\text{EDA}}^2 = \sum_i \left[\frac{nX_i(\mathbf{p}) - R_i}{\Delta R_i} \right]^2 + \left[\frac{nS - 1}{\Delta S / S} \right]^2$$

$$\left\{ \begin{array}{l} R_i, \Delta R_i = \text{relative measurement, uncertainty} \\ S, \Delta S = \text{experimental scale, uncertainty} \\ X_i(\mathbf{p}) = \text{observable calc. from res. pars. } \mathbf{p} \\ n = \text{normalization parameter} \end{array} \right.$$

Near a minimum of the chi-squared function at $\mathbf{p} = \mathbf{p}_0$,

$$\chi^2(\mathbf{p}) = \chi_0^2 + (\mathbf{p} - \mathbf{p}_0)^T \mathbf{g}_0 + \frac{1}{2}(\mathbf{p} - \mathbf{p}_0)^T \mathbf{G}_0(\mathbf{p} - \mathbf{p}_0)$$

$$= \chi_0^2 + \Delta\chi^2.$$

$$\left\{ \begin{array}{l} \chi_0^2 = \chi^2(\mathbf{p}_0) \\ \mathbf{g}_0 = \nabla_{\mathbf{p}} \chi^2(\mathbf{p}) \Big|_{\mathbf{p}=\mathbf{p}_0} \approx 0 \\ \mathbf{G}_0 = \nabla_{\mathbf{p}} \mathbf{g}(\mathbf{p}) \Big|_{\mathbf{p}=\mathbf{p}_0} \end{array} \right.$$

The parameter covariance matrix is $\mathbf{C}_0 = 2\mathbf{G}_0^{-1}$, and so first-order error propagation gives for the cross-section covariances

$$\text{cov}[\sigma_i(E)\sigma_j(E')] = \left[\nabla_{\mathbf{p}} \sigma_i(E) \right]^T \mathbf{C}_0 \left[\nabla_{\mathbf{p}} \sigma_j(E') \right] \Big|_{\mathbf{p}=\mathbf{p}_0}$$

$$= \Delta\sigma_i(E)\Delta\sigma_j(E')\rho_{ij}(E, E').$$

Parameter confidence intervals

It was proposed by Y. Avni [*Ap. J.* **210**, 642 (1976)] to define confidence intervals for the parameters of a fit by the condition

$$\Delta\chi^2 = \frac{1}{2} \Delta\mathbf{p}^T \mathbf{G}_0 \Delta\mathbf{p} \leq \Delta\chi_{\max}^2,$$

where $\Delta\chi_{\max}^2$ is chosen to give a particular confidence level (CL)

$$P(\Delta\chi^2 | k) = \left[2^{\frac{k}{2}} \Gamma\left(\frac{k}{2}\right) \right]^{-1} \int_0^{\Delta\chi_{\max}^2} t^{\frac{k}{2}-1} e^{-\frac{t}{2}} dt = \text{CL (e.g. } \sim 0.68 \text{ for } 1-\sigma, 0.95 \text{ for } 2-\sigma, \text{ etc.)}$$

for a chi-squared distribution with k degrees of freedom. Many statistical analysis (not necessarily physical science) applications use this method to determine parameter uncertainties (usually with CL = 95%, or 2- σ). For CL = 68% (1- σ), $\Delta\chi_{\max}^2 \approx k = \langle \Delta\chi^2 \rangle$. This results in 1- σ parameter confidence intervals, *

$$\Delta p_i \leq \sqrt{2\Delta\chi_{\max}^2 H_{ii}} = \sqrt{\Delta\chi_{\max}^2 C_{ii}^0} \approx \sqrt{k C_{ii}^0},$$

that are $\sim \sqrt{k}$ larger than the standard deviations (σ_{p_i}).

* when the remaining parameters are adjusted to obtain a new chi-square minimum

⁷Li system analysis

Channel	a_c (fm)	l_{\max}
$t+^4\text{He}$	4.02	5

$^6\text{Li}(n,n')^6\text{Li}^*$	$E_n = 3.35 - 4$	8	σ_{int}
$^6\text{Li}(n,d)^5\text{He}$	$E_n = 3.35 - 4$	2	σ_{int}
Total		3918	13

The EDA **R**-matrix analysis included data for all reactions open in the ⁷Li system at energies up to $E_n = 4$ MeV ($E_x = 10.7$ MeV). The data set, which included more than 3900 experimental points, is summarized in Table I. **The χ^2 per degree of freedom for the analysis is 1.36.** The original experimental uncertainties were not changed, but outlier points having $\chi^2 > 10$ were discarded from the fit.

^{17}O System: $^{13}\text{C}(\alpha,n)^{16}\text{O}$ S-factor

Recent development in EDA5 capability

- R-matrix fit to 20 MeV: 6 partitions; 93 channels; largest analysis
- $n^{13}\text{C}, n_1^{13}\text{C}^*, n_2^{13}\text{C}^*, \alpha^{10}\text{Be}, n_3^{13}\text{C}^*, nn^{12}\text{C}$

EDA6: modern Fortran implementation

- Improved physics capabilities
 - ▣ Enlarge channel space to extend energy range to >20 MeV
 - ▣ Hyperspherical approach to multiparticle break-up (total x-sec.)
- Data handling
 - ▣ Automated/integrated with CSISRS/EXFOR c4/c5 format
 - ▣ Data covariance standardization
- Fitting
 - ▣ Data covariance
 - ▣ Bayesian event-based maximum likelihood approach
- Exchange
 - ▣ ENDF-6 format/ACE/NDI/...
 - ▣ Resonance parameters: Brune alternative; ***T-matrix poles***

Brune parameters vs. T-matrix poles

- The Brune parameters are useful for exchange purposes

$$\mathcal{E} = e - \sum_c \gamma_c \gamma_c^T (S_c - B_c), \quad \mathcal{E} \mathbf{a}_i = \tilde{E}_i \mathbf{a}_i$$

- *But they depend on the channel radii; EDA & AMUR allow these to float*
- As a check of the observable equivalence of various analyses, finding the poles of the T-matrix isn't much more difficult

$$\det A(E) \Big|_{E=\{E_R\}} = 0 \quad A_{\lambda'\lambda}^{-1} = E_\lambda \delta_{\lambda'\lambda} + \Delta_{\lambda'\lambda} - i\Gamma_{\lambda'\lambda} - E \delta_{\lambda'\lambda}$$

- ENDF-6 format
 - Brune parameters (LRP=1, LRF=7): can be used to compute observables
 - T-matrix poles (LRP=2, LRF=7): are used for analysis comparisons
