

Task on the comparison of half-life data in the Y2K k_0 -database

In response to the task from the 1st RCM of the CRP on a “Reference Database for Neutron Activation Analysis” a comparative exercise of the half-lives used in the Y2K k_0 -database¹ has been made. This analysis involved a comparison of the quoted half-life to those present in the recently released JEFF-3.1 Radioactive Decay Data Library². The sources of the data were investigated and uncertainties included as these were not originally quoted for the k_0 -database. Other sources were investigated as appropriate, particularly the recent NUBASE evaluation³ which uses the ENSDF database as a source for much of its data.

Three tables are shown which present the results of this action.

Table 1 contains 13 nuclei where the differences between the libraries exceeds 0.5%, in some cases more significantly. Some of these cases show that the values used in the JEFF-3.1 library may not be the latest (see comment at the bottom of this page), but others also highlight possible shortcomings in the k_0 -database value. The Comments column in the table gives the date of the JEFF-3.1 evaluation, normally followed by similar details for the k_0 -database (referred to as “De Corte”).

Below is an attempt to comment more closely on the findings shown in Table 1.

- ^{20}F , ^{37}S and ^{51}Ti : all three probably highlight shortcomings in the JEFF-3.1 library.
- $^{105\text{m}}\text{Rh}$: very approximate data (generally with no uncertainty), should be investigated experimentally and very careful use should be made of any value.
- ^{109}Pd : JEFF contains a recent and very accurate value, knowing the origin of the De Corte value would be useful and/or JEFF should be adopted.
- ^{108}Ag : although the JEFF evaluation is relatively old a 2005 evaluation supports this value.
- $^{114\text{m}}\text{In}$: difference probably linked to age of JEFF evaluation.
- $^{113\text{m}}\text{Sn}$: large uncertainties exist for all evaluations. How does this actually affect NAA?
- ^{122}Sb : perhaps the more recent JEFF value should be adopted?
- $^{133\text{m}}\text{Ba}$: relatively large uncertainty on the quite old JEFF value, but not enough to justify the difference. Could a new measurement/evaluation of the half-life be made as the De Corte value is also quite old?
- ^{177}Lu : JEFF contains a very recent (2003) evaluation with reasonable uncertainty which matches NUBASE/ENSDF, hence knowing the origin of the De Corte value would be useful and/or JEFF should be adopted.
- ^{187}W : both are relatively old evaluations, but the difference is on the limit of relevance. Would a new measurement/analysis be justified?
- ^{186}Re : JEFF contains an accurate value from LNHB, but their 2004 re-evaluation supports the De Corte value.

Short comment on the JEFF-3.1 half-life values

The JEFF-3.1 Library was assembled from a number of different sources, a small number of which date back as far as 20 years or more, but most of which are much more recent. Due to the criterion

¹ F. De Corte, “The updated NAA nuclear data library derived from the Y2K k_0 -database”, Journal of Radioanalytical and Nuclear Chemistry, 257, No. 3, 493-499 (2003)

² See the OECD/NEA Databank website which deals with the JEFF Project:
http://www.nea.fr/html/dbdata/projects/nds_jef.htm

³ G. Audi, O. Bersillon, J. Blachot and A.H. Wapstra, “The NUBASE evaluation of nuclear and decay properties”, Nuclear Physics A, 729, 3-128 (2003)

for complete and consistent files to be taken as a whole, no attempt was made to update individual values (such as half-life) within these sources. Changing the value of the half-life in a data file containing full decay scheme information can have serious implications on the other data included, e.g. the $\log ft$ values, which would have also required updating. Unfortunately it was not possible to undertake such adjustments within the constraints imposed for its construction. It should therefore be noted that there may be some shortcomings in the half-life values included. This exercise is thus also useful for the JEFF Project as well as this CRP.

Data accuracy: All data from JEFF-3.1 are given to a maximum of three decimal places. Any less means that they are not required.

Table 2 contains 21 nuclei where differences are in the range from ~0.1% to 0.5%. Although these differences are generally on the same level as the quoted uncertainties, there are some for which the differences are significantly higher and these should be noted and probably examined more closely, *i.e.* ^{103}Ru , $^{134\text{m}}\text{Cs}$, ^{153}Sm , $^{152\text{m}}\text{Eu}$ and ^{159}Gd .

For completeness Table 3 contains the details of the comparison of all the nuclei quoted in the De Corte paper (including those extracted in Tables 1 and 2).

I would welcome any comments from CRP participants on this analysis.

Mark A. Kellett
