RESONANCE PARAMETERS FOR MEASURED keV NEUTRON
CAPTURE CROSS SECTIONS

by

A R de L. MUSGROVE

ABSTRACT

All available neutron capture cross sections in the keV region (~ 5 to 100 keV) have been fitted with resonance parameters. Capture cross sections for nuclides with reasonably well known average s-wave parameters, but no measured cross section, have been calculated and tabulated using p- and d- wave strength functions interpolated between fitted values. Several of these nuclides are of interest in the theory of slow nucleosynthesis of heavy elements in stars, and the product of cosmic abundance (due to the s-process) and capture cross section at 30 keV has been plotted versus mass number.

APPENDIX Some Calculated keV Capture Cross Sections in the range 5 to 100 keV

1. INTRODUCTION

In recent years much new data on radiative capture cross sections has become available, principally due to the pioneering work of R. L. Macklin, J. H. Gibbons and their associates at the Oak Ridge National Laboratory, (Macklin, Gibbons et al. 1961, 1962, 1965, 1967). It was discovered that the resonance parameters at present being used in the data libraries at the A.A.E.C. did not give good agreement with the experimental cross sections in a number of cases. It was therefore considered desirable to readjust the parameters to fit the latest measurements. Furthermore, the investigations in keV-averaged capture being performed at the A.A.E.C. require estimates of the s-, p- and d-wave contributions to the capture cross section to calculate the γ -ray intensities to low-lying states on the statistical model (Allen et al. 1969 - to be published). An attempt was therefore made to include d-wave partial cross sections and to give values for the d-wave strength function, S_2 . The adjustable parameters are the radiative capture width $\langle \Gamma_\gamma \rangle$, the average level spacing $\langle D \rangle$ and the s-, p-, and d-wave neutron strength functions, S_0 , S_1 and S_2 . Of these, the first three are usually known to within some probable error from low energy cross section measurements. This helps to tie down the s-wave contribution to the cross section and allows estimates to be made for the p- and d-wave contributions and hence for S_1 and S_2 .

The expected radiative capture cross sections have also been calculated in this survey for a number of nuclides which still await the experimenter. Only nuclides having fairly well known s-wave parameters are dealt with and values for S_1 and S_2 are interpolated between fitted values. (This is a better method of estimating unknown cross sections than direct interpolation (the usual method), especially where the relative cross sections of a number of isotopes of the same element are required. Several of these nuclidic capture cross sections are of importance to the theory of slow nucleosynthesis in Population II stars (Burbidge et al. 1957) where nuclides close to the line of β -stability are formed by neutron captures beginning with an original iron-group 'seed' nucleus.

2. AVERAGE RADIATIVE CAPTURE CROSS SECTIONS

In the energy range under discussion (5 to 100 keV), neutrons having angular momentum up to $\ell = 2$ contribute to the total capture cross section. The method of calculation of the ℓ -wave cross sections followed here is outlined by Gibbons et al. (1961) and based on the theory of Lane and Lynn (1957). Under the assumption that the average level spacing is greater than the average level widths such that resonances are not overlapping, the cross section for ℓ -wave neutron capture by a target nucleus of spin I into final states of spin J is given by:

$$\langle \sigma_{J\ell} \rangle = \frac{2\pi^2}{k^2} \langle \Gamma_\gamma \rangle S_\ell P_\ell \sqrt{E} \sum_J \frac{g_J \epsilon_{IJ}^\ell F(a_{\ell J})}{\langle \Gamma_J \rangle}, \quad (1)$$

where E is the incident neutron energy,

k is the neutron wave number,

P_ℓ is the ℓ -wave penetrability factor,

S_ℓ is the ℓ -wave neutron strength function,

and $F(a_{\ell J})$ is a correction term which enters when the average of the ratio $\Gamma_n \Gamma_\gamma / \Gamma$ is replaced by the ratio of the separate averages.

The penetrabilities are given by:

$$P_0 = 1$$

$$P_1 = x^2 / (1 + x^2),$$

and $P_2 = x^4 / (9 + 3x^2 + x^4)$, where $x = kR$ and R is the channel radius,

while $S_\ell = \frac{\langle \Gamma_{nJ}^\ell \rangle}{\langle D_J \rangle}$ where $\langle \Gamma_{nJ}^\ell \rangle$ is the average reduced neutron width.

The following assumptions are made:

(i) The s-wave neutron strength function $S_0 = \langle \Gamma_{nJ}^0 \rangle / \langle D_J \rangle$ is independent of J and is $\ll 1$.

(ii) The average resonance spacings are related by a $2J + 1$ dependence. Therefore:

$$D_J = \frac{2(2I+1)}{2J+1} D_{\text{obs}} = \frac{D_{\text{obs}}}{g_J},$$

where D_{obs} is the observed level spacing of s-wave levels at the neutron binding energy.

(iii) The radiative width Γ_γ is independent of J .

(iv) The radiative strength function $S_\gamma = \Gamma_\gamma / \langle D \rangle$ is independent of energy. This assumption should be approximately valid up to 100 keV (Musgrave 1968).

(v) Inelastic scattering is negligible.

(vi) The average neutron width per channel spin projection is independent of the channel spin $j = I \pm \frac{1}{2}$. This assumption produces the factor ϵ_{IJ}^ℓ in Equation 1.

(vii) The channel radius is given by $R = 1.35 A^{1/3}$ Fermis and is independent of J and ℓ .

(viii) The radiative width is independent of ℓ . This assumption is discussed in more detail below.

From these assumptions the following relations are obtained:

$$\begin{aligned} \langle \Gamma_J \rangle &= \langle \Gamma_{nJ} \rangle + \langle \Gamma_\gamma \rangle = \sum_j \langle \Gamma_{nJj} \rangle + \langle \Gamma_\gamma \rangle \\ &= \epsilon_{IJ}^\ell \langle \Gamma_{nJj} \rangle + \langle \Gamma_\gamma \rangle, \end{aligned} \quad (2)$$

$$\begin{aligned} \epsilon_{IJ}^\ell &= 2 \text{ for } |J - \ell| \leq I \pm \frac{1}{2} \leq J + \ell \\ &= 1 \text{ for } |J - \ell| \leq \text{either } (I + \frac{1}{2}) \text{ or } (I - \frac{1}{2}) \text{ but not both } \leq J + \ell \\ &= 0 \text{ otherwise,} \end{aligned} \quad (3)$$

$$\begin{aligned} \langle \Gamma_{nJ} \rangle &= \epsilon_{IJ}^\ell \langle \Gamma_{nJj}^\ell \rangle P_\ell \sqrt{E} \\ &= \frac{D_{\text{obs}}}{g_J} S_\ell P_\ell \epsilon_{IJ}^\ell \sqrt{E}. \end{aligned} \quad (4)$$

The correction factor $F(\alpha_{\ell J})$ is given by Reichel and Wilkins (1964) as

$$F(\alpha_{\ell J}) = (1 - \alpha_{\ell J}) \left[1 - \frac{\pi \alpha_{\ell J}}{2} \operatorname{erf} \left(\frac{\alpha_{\ell J}}{2} \right) \exp \left(\frac{\alpha_{\ell J}}{2} \right) \right], \quad (5)$$

where $\alpha_{\ell J} = \Gamma_\gamma / \langle \epsilon_{IJ}^\ell \Gamma_{nJj} \rangle$,

and $\operatorname{erf}(Z) = \frac{2}{\sqrt{\pi}} \int_0^Z e^{-t^2} dt$.

3. ANALYSIS

All available keV capture cross sections for separated isotopes appearing in the compilation of Goldberg et al. (1966) were fitted with resonance parameters. Further cross section determinations are tabulated in Macklin and Gibbons (1965, 1967). Average level spacings and radiative widths were mostly estimated from Goldberg et al. (1966). Strength functions for s-wave neutrons were taken from Seth (1966) and the CINDA catalogue (1968) while initial estimates for S_1 were taken from Seth et al. (1964) where some values for S_2 are also to be found.

As a first guess it was assumed that the s- and d-wave strength functions were equal since, from the optical model, peaks in S_2 are expected in the same mass regions as those in S_0 . No claim is made for the uniqueness of the parameters derived, since only the ratio $\Gamma_\gamma/\langle D \rangle$ is of importance in determining the cross sections. When adjustments to this ratio have been made the alterations to Γ_γ and $\langle D \rangle$ have necessarily been somewhat subjective. Nevertheless an attempt has been made to keep this adjustment within the probable uncertainty associated with the low energy data. *met*

Furthermore, in some mass regions the d-wave contribution to the cross section is negligible, and the fitted value of S_2 is an order of magnitude estimate only. Table 1 gives the readjusted value for the parameters Γ_γ , $\langle D \rangle$, S_0 , S_1 and S_2 as well as the radiative strength function, S_γ . Figure 1 shows a plot of S_γ and S_0 versus mass number, these parameters being the determining factors of the s-wave cross section, while Figures 2 and 3 show the fitted values of S_1 and S_2 along with the elemental values given by Seth et al. (1964).

In the mass region 90 to 100, which corresponds to a peak in the p-wave strength function, we obtain some rather large values for S_1 . Seth et al. (1964) point out that such large values are inconsistent with their measurements of $\langle \sigma_t \rangle$, the average total cross section. However there is some evidence in this region for the non-equality of s- and p-wave radiative widths. Morgenstern et al. (1968) give $\ell = 0$ values for Γ_γ in Zr91+ n and Nb93+ n of 110 and 145 meV respectively and $\ell = 1$ values of 310 and 210 meV. If this trend is general in this region, the quoted values for S_1 would be considerably reduced. Assumption (viii) above is in fact rather weak but has been made to reduce the number of fitting parameters. *?*

4. CALCULATIONS

With interpolated values of S_1 and S_2 , s-wave parameters derived from low energy measurements (Goldberg et al. 1966) and parameters for germanium isotopes from Malecki et al. (1967), cross sections have been calculated for a number of nuclides for which measurements have not yet been carried out. The calculated cross sections and the parameters used in the calculation are shown in the Appendix. The cross sections are in millibarns and energy is in keV. This data will be transmitted to the I.A.E.A. Nuclear Data Unit at Vienna and copies may be obtained from that organization. *App. ↓ DK*

Figures 4 and 5 show calculated and measured values for the cross section at 30 keV plotted against mass number for odd-A and even-A compound nuclei respectively. The effect of shell structure is clearly evident.

5. STELLAR NUCLEOSYNTHESIS

Burbidge et al. (1957) demonstrated that neutron capture processes in stars have played the principal role in the build-up of all the heavy elements beyond the iron-group abundance peak. Two different and independent processes were required to explain the observed abundances. The first of these, the so-called r-process occurs on a rapid time scale (about 100 neutron captures in 1 to 100 seconds) and since the intervening nuclei have no time to decay by β -decay, very neutron-rich nuclides are synthesised in this process and subsequently undergo β -decays to reach stability. This process may have occurred in rapid supernova explosions or possibly in rapidly evolving massive stars ($> 10^4$ sun masses) associated with extended and quasi-stellar objects (Seeger et al. 1965).

The s-process, on the other hand, occurs on a slow time scale (1 neutron capture in 10^3 to 10^6 years) and consequently the path of this process lies along the β -stable valley of the nuclides. This process is thought to take place in red giant stars with an effective temperature for the reaction in the region of 3×10^8 °K (30 keV).

Most nuclides have been formed by both processes and the separation of the s- and r-process contributions is difficult. However certain nuclei have been formed either solely or predominantly by one or other process and it is these nuclides which serve as useful tests for the theory. The s-process is governed by the set of differential equations (one for each mass number):

$$\bullet \quad \frac{dN_A}{dt} = -\phi_n (\sigma_A N_A - \sigma_{A-1} N_{A-1}), \quad (6)$$

where ϕ_n is the neutron flux, N_A is the abundance of the stable isobar at mass number A (on the s-process path) and σ_A is its neutron capture cross section at an appropriate temperature. A plot of $\sigma_A N_A$ versus A gives a characteristic ledge and precipice structure. $\sigma_A N_A$ is approximately constant when dN_A/dt is small compared with either of the terms of the right-hand side of the equation, that is, in regions of reasonably high cross section. However at magic numbers, where the cross section suddenly falls, dN_A/dt is comparable to $\sigma_{A-1} N_{A-1}$ (magic) and $\sigma_A N_A$ is then constant along a new and lower ledge.

A number of the nuclides for which we have calculated cross sections lie on the s-process path and accordingly we have computed the product σN_s , where N_s is the cosmic abundance due to the s-process, and plotted it versus mass number. Table 2 shows the nuclides and their cosmic abundances relative to a silicon abundance of 10^6 . In the column labelled 'formation process', s-only indicates nuclides formed solely in the s-process, s indicates a nuclide for which s-process abundance \gg r-process abundance, while fractions indicate the approximate contribution from the s-process. The fourth column gives the cross section at 30 keV, asterisks indicating measured values, while in the final column the product σN_s is given. This information is plotted in Figure 6 in two ways: dots indicate s or s-only nuclides with measured or calculated cross section, triangles indicate nuclides where the s-process contribution has been estimated (for example $\frac{1}{2}s$), while nuclides for which the s-process contribution is uncertain are not plotted. The latter points have no direct bearing on the curve and are inserted merely to indicate how far above the σN_s curve they lie.

While no correction has been made in our points for the small r-process contributions to nuclides formed predominantly by the s-process, our calculated gallium and germanium cross sections indicate a ledge at mass number of about 70 and our values for the cadmium and indium σN_s fall closer to the observed trend than those estimated by other authors. The situation between mass numbers 140 to 200 is rather confused with some σN_s values around mass number 180 being about a factor of 2 too large. Further clarification of the s-process in this region must await better experimental cross section measurements.
