Production of Fp Group Constants for Fast Reactors
with Cook's Evaluated Data

Yasuyuki KIKUCHI, Kanji TASAKA, Hideo NISHIMURA,
Akira HASEGAWA and Satoru KATSURAGI

Japanese Nuclear Data Committee, JAERI

(Received November 21, 1973)

A set of group constants of 184 FP nuclides was produced with the evaluated data by Cook. They are lumped to those of a pseudo FP nuclide at various burn-up stages, with using the concentrations as weights. The concentrations were calculated by solving the beta chain equations with the yield data compiled by Meek and Rider.

Some anomalous behaviors were observed at the resonance energy region and the method for evaluating the resonance structure is briefly discussed.

Cook による評価データに基づく F P 高速炉用炉定数の作成

日本原子力研究所 シグマ研究委員会

(1 9 7 3 年 1 1 月 2 1 日受理)

Cook による評価データを用いて，184核種の核分裂生成物の群定数が作成された。これらの群定数は，燃焼状態に応じての濃度を重みとして，一つの凝核種の群定数にランプされた。濃度は β -チェイン方程式を解いて求められた。生成率としては，Meek と Rider の収集した値を用いた。

この群定数において，共鳴エネルギー領域で，いくつかの異常な傾向が発見された。この原因となる共鳴領域の評価方法について議論された。

1. Introduction

A set of group constants with 25 or 70 groups (JAERI Fast set)⁽¹⁾ was produced at Japan Atomic Energy Research Institute in 1970. This set has been widely used as the standard set in Japan. At that time, however, no evaluated data of the fission product nuclides were available, and therefore the values in the ABBN set⁽²⁾ has been temporarily adopted. Now the role of fission products becomes more important in the fast reactor calculation, as prediction of the detailed burn-up characteristics is required in design works.

The FP group constants are generally lumped to those of a pseudo FP nuclide. This makes the problem more difficult. The lumped FP group constants depends not only on the nuclear data but also on the concentration which varies with burn-up condition. Such detailed informations are not clear for the ABBN-set nor for some other sets^(3, 4, 5) produced in other countries. Hence it has been much required to produce a new set of FP group constants by ourselves.

From this situation, Japanese Nuclear Data Committee (JNDC) started the evaluation of the FP data. While this evaluation proceeded, we examined the FP data already evaluated in other countries as another working group of JNDC (Fast FP Reactor Constants Working Group). We decided to produce a set of group constants with these evaluated data in order to respond the urgent request from users. The results are given in this report. When the evaluation by JNDC is completed, the present FP group constants set will be revised.

A brief discussion is given in Section 2 on the available evaluated data set. The method for producing the FP group constants is described in Section 3. The reliability of these group constants is discussed in Section 4.

2. Available Evaluated Data Set

The following evaluated data sets of fission product nuclides are now available in Japan.

1) Data evaluated by Cook⁽⁶⁾:

σ_T , σ_{el} , σ_{nonel} , σ_{inel} , $\sigma_{n\gamma}$ and $\sigma_{transport}$ for 184 nuclides* ($10^{-3} \text{ eV} \leq E \leq 15 \text{ MeV}$)

2) Data evaluated by Benzi and Reffo⁽⁷⁾:

$\sigma_{n\gamma}$ for 142 stable nuclides ($1 \text{ keV} \leq E \leq 10 \text{ MeV}$).

3) Data evaluated by Benzi et al.⁽⁸⁾:

σ_{inel} , $\sigma_{n,2n}$ and $\sigma_{n\gamma}$ for 18 nuclides
($1 \text{ keV} \leq E \leq 10 \text{ MeV}$)

4) ENDF/B version III⁽⁹⁾ for 27 nuclides

These evaluated data were plotted on a same graph to be compared with each other.

We found good agreements for nuclides of which plenty of experimental data exist.

As an example, capture cross section of ^{103}Rh is shown in Fig. 1. On the other hand, there are large disagreements among the evaluated data for nuclides whose experimental data do not exist. The case of ^{135}Cs is shown in Fig. 2.

It is not possible from this comparison to decide which evaluated data are the most reliable. Then we took the Cook's data set from the following reasons:

* Cook's evaluated data contains 184 ground state nuclides and 8 metastable nuclides.

There are some tape troubles, however, on the files of the metastable nuclides, and therefore only ground state nuclides are considered.

- 1) The largest number of nuclides is contained.
- 2) All the required reaction types are contained.
- 3) The data below 1 keV are also contained.
- 4) It seems better to use the data of the same origin, considering the systematic error in the evaluation.

The evaluation method adopted by Cook has some drawbacks in the resonance region.

This problem will be discussed in Section 4.

3. Production of FP Group Constants

The original Cook's data sent from CCDN were converted from the UKNDL format to the ENDF/A format because of the requirement of our processing code. Then $\bar{\tau}_T$, $\bar{\rho}_{el}$, $\bar{\rho}_{inel}$ and $\bar{\rho}_m$ of 184 nuclides were processed to the group constants with the PROF-GROUCH-G code⁽¹⁰⁾. The group structure is the same as that of the JAERI Fast set with 25 or 70 groups.

The weighting flux is assumed to be $1/E$ spectrum below 1 MeV and to be fission spectrum above 1 MeV. The fission spectrum is assumed as:

$$\phi(E) = A_0 e^{-E/A_1} \sinh \sqrt{A_2 E},$$

where A_0 , A_1 and A_2 are 4.84×10^{-7} , 1×10^6 and 2×10^{-6} respectively.

Neither the angular distribution nor the energy distribution is given in the Cook's data set, but $\bar{\mu}$ was found to be $2/3A$ from the comparison between the transport cross section and the total cross section. Hence the elastic removal cross section can be calculated with assuming the isotropic scattering in the center of mass system.

As for the inelastic scattering matrix, the energy distribution was determined with the evaporation model as:

$$F(E) dE = \frac{E}{T^2} e^{-E/T} dE.$$

The same nuclear temperature (T) was taken for all the nuclides and was determined to be 0.638 MeV with averaging the values recommended by Gilbert and Cameron⁽¹¹⁾.

The group constants of an individual FP nuclide are not generally used for the actual calculation, but are lumped to those of a few pseudo FP nuclides by using the concentration of each nuclide as the weighting factor.

The concentration was calculated with the FP-S code⁽¹²⁾ which solves the beta-decay

chain with Bateman's equation. The transfer from one beta-decay chain to another chain by neutron capture reaction is neglected in this code. The fission yield data were taken from the compilation by Meek and Rider⁽¹³⁾.

As the total number of FP nuclides is more than 700, the number of 184 is not enough to obtain the lumped group constants. If a nuclide is not contained in the Cook's data set, the concentration of this nuclide was added to that of the next nuclide in the beta-decay chain, i.e., the cross sections of the neighboring nuclides are assumed to be the same. The error of this approximation is expected to be small, because such nuclides not contained in the Cook's set are generally short-lived and their concentrations are small.

Three types of the lumped group constants were produced. They correspond to the fission products due to ^{235}U fission with thermal neutrons, to ^{239}Pu fission with thermal neutrons and to ^{238}U fission with fission spectrum neutrons.

The lumped group constants varies through burn-up accompanied by the change of the concentration. Therefore we gave them for burn-up of 1, 30, 60, 180, 360 and 720 days.

The multi group cross sections are tabulated in Appendix 1. The inelastic scattering matrices are tabulated in Appendix 2. These matrices are common for all the burn-up stages and for all the fission types(i.e. due to ^{235}U fission, to ^{239}Pu fission and to ^{238}U fission). The group constants due to ^{239}Pu fission are shown in figures of Appendix 3. The concentration of the pseudo FP nuclides are tabulated in Appendix 4 for various burn-up stages.

Discussion

The following trends can be pointed out from the figures in Appendix 3.

- 1) The elastic scattering cross sections have little burn-up dependence except in the resonance region. This indicates that the elastic scattering cross section is nearly the same among isobar nuclides, as expected from the optical model.
- 2) The capture cross sections increase with burn-up time, but nearly reach the saturated values after several ten days. It was found by Otake⁽¹⁴⁾ that the chains with mass number A=95, 99, 103, 131, 133 and 147 had remarkable contribution.
- 3) Evident discontinuity of energy dependence is observed at 4.65 keV.

Cook's group constants were lumped with even-A nuclides and with odd-A nuclides separately, in order to know where this discontinuity comes from. The results for capture cross section are shown in Fig. 3. We can point out the following two problems from these figures.

- a) The discontinuity is due to the odd-A lump.
- b) Time dependence of the even-A lump is anomalously large in the energy range from 465 eV to 1 keV.

These two problems (a and b) were investigated by Kikuchi⁽¹⁵⁾ and were found to be caused by the method for evaluating the resonance structure. In Cook's evaluation, the cross section was calculated with the statistical model in the high energy region. In the resonance region, on the other hand, the cross section was calculated with the resonance parameters. For nuclides whose resonance parameters are not experimentally known, Monte Carlo method was used to produce them so as to fit the calculated resonance integral to the experimental data if they exist⁽¹⁶⁾.

The cross section thus obtained may be suitable for thermal reactor calculations, as the resonance integral takes the important role in reactor calculations. On the other hand,

this method has the following drawbacks:

- 1) A very strong resonance appears sometimes at several hundred eV for an even-A nuclide because of the random sampling biased to fit the resonance integrals. If this happens to a radioactive nuclide, the effect of the strong resonance changes drastically with burn-up according to the change of the concentration. The large time dependence of the even-A lump was found to be caused by the strong resonance of ^{140}Ba as shown in Fig. 4.
- 2) The cross section curve has often large discontinuity at the connecting energy point between the statistical model calculation and the Monte Carlo calculation. The case of ^{90}Sr is shown in Fig. 5. This discontinuity itself is not anomalous, as we cannot say whether the connecting point fall at the peak or at the valley of resonance. However, the discontinuity of the lumped group constants is too large to be explained as the statistical fluctuation⁽¹⁵⁾. We found such a systematic discontinuity not caused by the position of resonance in Cook's evaluated data. For example, the capture cross section of ^{99}Tc is shown in Fig. 6. We cannot explain this systematic discontinuity.

These two drawbacks cause rather severe problem for fast reactor calculations, as these anomalous trends appear at the energy range which is important for fast reactors.

It was also pointed out by Kikuchi that the standard deviation of the cross sections was much reduced through the lumping process, as the errors cancell each other. Hence in order to avoid these anomalies, he proposed to extrapolate the statistical calculation to the resonance energy region, where this model is not applicable for an individual nuclide any longer. His proposed method is taken into account in the evaluation by JNDC.

Summary

A set of group constants of 184 FP nuclides was produced from the data evaluated by Cook, and was processed to lumped group constants of a pseudo FP nuclide.

This set has fairly anomalous energy dependence and time dependence, partly due to the evaluation in the resonance region. We are now preparing to revise this set with the newly evaluated JNDC data.

Acknowledgement

The authors thank the members of JNDC Fast FP Reactor Constants Working Group^{*} for their cooperation and helpful discussion. They also thank Mr. Sasamoto for his help to use the FP-S code. The general advice from the members of JNDC Fast FP Nuclear Data Working Group is also much appreciated.
