JAERI-M reports, issued irregularly, describe the results of research works carried out in JAERI. Inquiries about the availability of reports and their reproduction should be addressed to Division of Technical Information, Japan Atomic Energy Research Institute, Tokai-mura, Naka-gun, Ibaraki-ken, Japan.

Evaluation of Neutron Nuclear Data for ^{233}U
in Thermal and Resonance Regions

Division of Physics
Tokai Research Establishment
JAERI

Yasuyuki KIKUCHI

(Received January 22, 1981)

The thermal and resonance cross sections of ^{233}U were evaluated for JENDL-2. The cross sections below 1 eV are given as point-wise data and were evaluated by the use of the measured fission and capture cross sections. The resolved resonance parameters are derived up to 100 eV. The parameters were obtained by using NDES so as to reproduce the measured total and fission cross sections. The cross sections from 100 eV to 30 keV are represented by the unresolved resonance parameters. The fission and capture resonance integrals calculated from these parameters are 771 and 138 barns, respectively, which agree with the measured data within the quoted errors.

1. Introduction

In the thorium fuel cycle, ^{233}U has an essential role as a main fissile material. In spite of its importance, there still remain large uncertainties in the evaluated nuclear data of ^{233}U . For example, McNeamy and Jenkins¹⁾ pointed out from their benchmark tests that the cross sections of ^{233}U in ENDF/B-IV had some errors in the epithermal region.

Considering such a situation, the cross sections of ^{233}U were evaluated in the full energy range for JENDL-2. As ^{233}U is expected to be used in a thermal breeder reactor because of its high η -value in the thermal energy region, the thermal and resonance cross sections, as well as the cross sections for fast neutrons, were carefully evaluated.

In the evaluation for JENDL-2, the thermal and resonance cross sections were evaluated by the present author, and the cross sections in the higher energy range were evaluated by Asano and Matsunobu. The outline of the evaluation for full energy range will be published²⁾ elsewhere. Hence this report describes detailed evaluation procedure and gives the numerical results in the thermal and resonance regions.

The cross sections below 1 eV, given as point-wise data, are described in Chapter 2. The cross sections are represented by the resolved resonance parameters between 1 and 100 eV and by the unresolved resonance parameters between 100 eV and 30 keV. The evaluations of both parameters are described in Chapters 3 and 4, respectively.

2. Thermal Cross Sections

The cross sections below 1 eV are given as point-wise data, for the cross section values cannot be reproduced satisfactorily with the single-level resonance parameters in this energy range because of interference effects among levels.

The fission cross section was evaluated on the basis of recently measured data by Pschenichny et al.³⁾, Deruytter and Wagemans⁴⁾, Weston et al.^{5,6)} and Cao et al.⁷⁾. The capture cross section was also evaluated on the basis of measured data by Weston et al.⁵⁾. The evaluation was made by using NDES (Neutron Data Evaluation System)⁸⁾. In this system, numerical experimental data are displayed in a graphic form on a cathode-ray tube, and any point on the graph can be recorded in the computer memory by using a cross-hair cursor. Thus the evaluation with the eye-guide method can be made easily with this system.

The elastic scattering cross section was calculated from the resonance parameters with assuming the effective scattering radius of 9.93 fm which was obtained from analyses of the unresolved resonance parameters as will be described later. The 2200 m/s values of the evaluated cross sections agree with the values recommended by Lemmel⁹⁾ within the quoted errors. The total cross section given as a sum of the partial cross section agrees with the recent measurements^{3,10,11,12)} within their scatter.

The cross sections thus evaluated are given in Table 1. The evaluated cross section curves are compared with the measured data in Figs. 1 ~ 4.

3. Resolved Resonance Parameters

3.1 Status of Measured Data

The resonance parameters measured after publication of BNL-325 2nd edition¹³⁾ were surveyed through CINDA-76/77 and CINDA-78¹⁴⁾. The status of the measured data is shown in Table 2. The measured resonance parameters were stored in the REPSTOR system¹⁵⁾, and were compared with one another.

The measurements of the resonance cross sections were also surveyed through CINDA-76/77 and CINDA-78. The survey was restricted to data whose numerical values were available in NEUDADA file, since the energy points are very numerous in these data of the resonance cross sections. The status of the measured data is shown in Table 3.

3.2 Deduction of Complete Sets of Parameters

A total of 8 sets of the measured resonance parameters were examined. In the present work, only the parameters for the single-level Breit-Wigner formula were considered because of limitation in the processing codes. Thus the sets deduced by de Saussure et al.¹⁸⁾ and Cao et al.⁷⁾ were omitted. The sets by Felvinci and Melkonian¹⁷⁾ and by Sauter and Bergen²⁰⁾ were also abandoned, because these parameters were very discrepant from the remaining ones. Finally we considered the parameter sets deduced by Nizamuddin and Blons¹⁶⁾, by Kolar et al.¹¹⁾, by Ryabov et al.¹⁹⁾ and by Bergen and Silbert²¹⁾ in the present work.

All the necessary parameters were not given by the experimenters as seen in Table 2. In order to calculate the resonance cross sections, the parameters not given by the experimenters were estimated as follows:

- a) Nizamuddin and Blons¹⁶⁾

They gave the parameters for 169 levels, 33 of which are artificial

levels deduced to partially compensate the interference effects among levels. They gave Γ , Γ_f and $\sigma_0 \Gamma_f$ for the real levels, and Γ and $\sigma_0 \Gamma_f$ for the artificial levels. Taking account of the relation

$$\sigma_0 \Gamma_f = \frac{2\pi}{\lambda^2} g \frac{\Gamma_n \Gamma_f}{\Gamma}, \quad (1)$$

we had for the real levels

$$\Gamma_n = 2g\Gamma_n = (\sigma_0 \Gamma_f) \lambda^2 \Gamma / \pi \Gamma_f, \quad (2)$$

$$\Gamma_\gamma = \Gamma - \Gamma_f. \quad (3)$$

The values of Γ_γ were found to be 39 meV for all the real levels. For the artificial levels, Γ_f was obtained by assuming the same value of Γ_γ as the real levels,

$$\Gamma_f = \Gamma - \Gamma_\gamma (= 39 \text{ meV}), \quad (4)$$

and Γ_n was obtained from Eq. (2).

b) Kolar et al.¹¹⁾

They gave Γ and $2g\Gamma_n^\circ$ from their transmission measurements. By assuming $\Gamma_\gamma = 39$ meV according to Nizamuddin and Blons, we obtained

$$\Gamma_n = 2g\Gamma_n = 2g\Gamma_n^\circ \sqrt{E},$$

$$\Gamma_f = \Gamma - \Gamma_n - \Gamma_\gamma.$$

c) Ryabov et al.¹⁹⁾

They gave $2g\Gamma_n$ and Γ from their measurements on the total, fission and capture cross sections, but detailed information was not available.

Assuming $\Gamma_\gamma = 39$ meV, we obtained

$$\Gamma_n = 2g\Gamma_n,$$

$$\Gamma_f = \Gamma - \Gamma_n - \Gamma_\gamma.$$

d) Bergen and Silbert²¹⁾

They obtained $2g\Gamma_n^o$ and Γ_f from the measurements of the fission and capture cross sections by using the underground nuclear detonation as a neutron source. By assuming $\Gamma_\gamma = 45$ meV as they assumed in their analysis, we had

$$\Gamma_n = 2g\Gamma_n^o = 2g\Gamma_n^o \sqrt{E}$$

$$\Gamma = \Gamma_f + \Gamma_\gamma + \Gamma_n.$$

3.3 Evaluation of Parameters

3.3.1 Comparison of Parameter Sets

The four sets of the parameters above mentioned were compared with one another and with the parameters of ENDF/B-IV. It is difficult, however, to compare each quantity of the parameters with one another directly, because a quantity is correlated with the others in the analysis. For example the value of Γ_n is dependent on the value of Γ_γ , when it is deduced from the transmission measurements.

In the present work, the areas of each resonance and the calculated cross sections were compared. For comparison of the fission or capture area, we calculated A_f and A_c defined as

$$A_f = 2g \frac{\Gamma_n \Gamma_f}{\Gamma}, \quad A_c = 2g \frac{\Gamma_n \Gamma_\gamma}{\Gamma}.$$

Table 4 compares the values of A_f and A_c summed up over levels located in adequate energy ranges. The areas calculated from the parameters of Nizamuddin and Blons¹⁶⁾, Kolar et al.¹¹⁾ and ENDF/B-IV agree well with one another within the error of 20 %, while the areas of Bergen and Silbert²¹⁾ are very large and those of Ryabov et al.¹⁹⁾ are extremely small.

The total, fission and capture cross sections were calculated from these 5 sets with the RESENDD code²⁷⁾ and are compared with one another in Figs. 5 ~ 7, respectively. The set of Bergen and Silbert gives the largest values for all the cross sections. Small resonances seem to be missed in the set of Ryabov et al.

3.3.2 Initial Guess Parameters

From the comparisons mentioned above, we omitted the parameter sets of Bergen and Silbert and of Ryabov et al., because Bergen and Silbert deduced parameters from the larger cross sections than the recently measured ones, and Ryabov et al. missed small resonances. As to the remaining two sets, we concluded that the set of Nizamuddin and Blons was more reliable, because their parameters were deduced not only from the high resolution measurements of the fission cross section by Blons²⁶⁾ but also from the transmission measurements by Kolar et al.¹¹⁾ from which the parameters of Kolar et al. were deduced. Thus the set of Nizamuddin and Blons was adopted as the initial guess parameters. In the energy range below 6 eV, where Nizamuddin and Blons did not give the parameters, the recommended data in BNL-325 3rd edition²⁸⁾ were adopted as the initial guess.

3.3.3 Modification

The cross sections were calculated from the initial guess parameters with assuming the effective scattering radius of 9.93 fm. The calculated total and fission cross sections agree well with the measured data within their scatters in most of energy range. It should be noted that the calculated capture cross section agrees well with the measured data

of Weston et al.⁶⁾, though the resonance parameters were deduced without considering the capture data. This suggests applicability of the parameters of Nizamuddin and Blons.

In some energy ranges, however, agreement was not satisfactory between the calculated and measured cross sections. The resonance parameters were modified so as to reproduce the measured data in such energy ranges by displaying the calculated cross sections and the measured data on a cathode ray tube with NDES. Figures 8 and 9 show improvement of agreement in total and fission cross sections, respectively, by modification of the resonance parameters.

The parameters of the lowest five levels were further modified so as to reproduce the measured data of fission and capture resonance integrals.

3.3.4 Background Cross Section

Even after modifying the resonance parameters, the calculated fission cross section failed to reproduce the measured data in limited energy ranges particularly in valleys between resonances. This is caused by the interference among resonances and cannot be resolved even by adoption of the artificial levels. The multi-level formula is essentially required for such a fissile nuclide as ^{233}U . In the present work, however, the discrepancies were corrected by applying a positive or negative background cross section to the fission cross section. This work was made also by using NDES. No background correction was applied to the capture and elastic scattering cross sections. Figure 10 shows the fission cross sections calculated with and without the background cross section as well as the measured data in the energy range between

13 and 16 eV. The background fission cross section is tabulated in Table 5.

3.3.5 Results

The evaluated resonance parameters are listed in Table 6 with the measured data and the evaluated ones in BNL-325 2nd and 3rd edition and in ENDF/B-IV. The calculated total, fission and capture cross sections are shown with the measured data in Figs. 11 ~ 13, respectively. Satisfactory agreement is observed in full energy range, when the background cross section is applied.

4. Unresolved Resonance Parameters

The unresolved resonance parameters were deduced by the ASREP code²⁹⁾ so as to reproduce the total, fission and capture cross sections evaluated by Asano and Matsunobu²⁾ on the basis of measured data. The total cross section was evaluated by averaging the data of Pattenden et al.²⁴⁾ and Kolar et al.¹¹⁾ The fission cross section was taken from the measurements by Blons²⁶⁾. The capture cross section was evaluated on the basis of the measured data of Weston et al.⁶⁾ and of Hopkins and Diven³⁰⁾ by the aid of the statistical model calculation.

First we searched for the s- and p- wave strength functions, the fission widths and the effective scattering radius so that the global trends of the total, fission and capture cross sections might be well reproduced. The observable level spacing (D_{obs}) and the radiation width (Γ_γ) were fixed to be 0.68 eV and 39 meV, respectively. The energy dependence of the level spacing was calculated with the level density parameters given by Gilbert and Cameron.³¹⁾ The ratio of the s- wave to

p- wave strength function was fixed to be 0.79 as obtained from the optical model calculation, and the spin dependence of the fission widths was also fixed as expected³²⁾ from the channel theory of fission. The effective scattering radius of 9.93 fm was obtained as the results of this search. The strength functions and fission widths thus determined were used as the initial guess parameters in the next step.

Then we searched for the s- and p- wave strength functions and the fission widths with fixing the other parameters so as to reproduce the total, fission and capture cross sections at each energy point. The ratios of s- wave to p- wave strength function and of the fission widths for each spin state were also fixed in this search.

The unresolved resonance parameters thus obtained are given in Table 7 with the calculated cross sections. The energy dependence of the strength functions and the fission widths are shown in Fig. 14 as the ratios to the initial guess values. The fluctuations are considerably large below 1 keV and there seem to exist tendencies to increase with increasing energy in both strength functions and the fission widths.

5. Discussion

The point-wise cross sections were calculated from the resonance parameters and the background cross sections in the energy range from 10^{-5} eV to 30 keV. The fission and capture resonance integrals were calculated from these cross sections by numerical integration, and are compared with the measured data in Table 8. The calculated values agree with the measured data within the quoted errors. This suggests applicability of the present data to thermal reactor calculations.

The same values of the effective scattering radius are used

in the thermal, resolved resonance and unresolved resonance regions. This suggests the consistency of the evaluation in these three energy regions.

6. Conclusions

The thermal and resonance cross sections of ^{233}U were evaluated for JENDL-2. The cross sections below 1 eV were given as point-wise data, and the resonance cross sections were represented by the resonance parameters and the background cross sections.

The resolved resonance parameters were evaluated by using NDES where the calculated resonance cross sections could be compared immediately with the measured data in the graphical form. The background corrections were made on the fission cross section in the very restricted energy regions where the calculation could not reproduce the measured data because of the strong interference among levels. The unresolved resonance parameters were obtained up to 30 keV so as to reproduce the evaluated total, fission and capture cross sections. No background correction was applied in the unresolved resonance region.

The evaluated cross sections agree very well with the measured data, and the calculated resonance integrals reproduce the measured data within the quoted errors. Hence the presently evaluated data are expected to be applicable to the thermal reactor calculations in the thorium fuel cycle.

Acknowledgment

The author wishes to thank T. Nakagawa for his aid to use NDES. He also acknowledges N. Asano and H. Matsunobu for his discussion on the evaluation of the cross sections in the unresolved resonance region. Careful typewriting by H. Terakado is much appreciated.

124.12		260 ±50			221	GFS= 39	74NIZAMUDDIN

* Mark A denotes that the value is $2g\Gamma_n$

** Symbols in miscellaneous column

L : orbital angular momentum of incident neutrons

WGO: $2g\Gamma_n^*$

WW5: $g\Gamma_n\Gamma_\gamma/\Gamma$

WCM: $g\Gamma_n$

GFS: $\sigma_0\Gamma_f$

Table 7 Unresolved resonance parameters and calculated cross sections of ^{233}U .
 Fixed parameters: $R = 9.93 \text{ fm}$ and $\Gamma_\gamma = 39 \text{ meV}$.
